Abstract

New classical integrable systems of Camassa-Holm peakon type are proposed. They realize the maximal even piecewise- D_2 generalization of the Calogero-Françoise flows, yielding periodic and pseudoperiodic trigonometric/hyperbolic potentials. The associated r -matrices are computed. They are dynamical and depend on both sets $\{p_i\}$ and $\{q_i\}$ of canonical variables.

1 Introduction

Classical r -matrices for the Lax representation of Liouville-integrable systems, depending on some of the canonical variables (so called “dynamical r -matrices”), have been the subject of

¹e-mail: avan@u-cergy.fr

²e-mail: rollet@u-cergy.fr

a very extensive set of studies in these past years, starting with the first mention of their relevance [1], and their use in non-ultra local Poisson algebras [2, 3].

Most studies afterwards have been concerned with a subset of such matrices, obeying the so-called “dynamical Yang Baxter algebra”. A paradigmatic example occurred in the Calogero-Moser r -matrix formulation [4], and classification theorems were extensively developed, see for instance [5]. These matrices depend only on one half of Poisson-commuting canonical variables (either momenta or positions), identified in the general theory [6] as coordinates on the dual of an Abelian Cartan algebra. The non-abelian situation is discussed in e.g. [7].

The above-mentioned associated dynamical classical Yang Baxter equation, obtained as a sufficient consistency condition for associativity of the Poisson brackets, can then be related to dynamical quantum algebras such as the Gervais Neveu Felder (GNF) algebra [8, 6] or the dynamical reflection algebras [9, 10, 11].

More precisely: the clearest case is provided by the Ruijsenaars-Schneider quadratic Poisson structure involving two matrices [12, 13]. One is then able [13, 10, 9] to identify the consistency equations as a classical limit of the Yang-Baxter equations for a dynamical reflection algebra. They include in particular the quantum Gervais Neveu Felder cubic equation (symbolically written $RR^hR = R^hRR^h$) for e.g. Interaction Round a Face (IRF)-type quantum R -matrices, and its associated adjoint equation $RSS^h = SS^hR$. It is interesting to remark that the first mentioned example, i.e. the scalar Calogero Moser r -matrix, obeys in fact a consistent combination of these two equations.

Even in such cases when the r -matrix or matrices depend on Poisson-commuting dynamical variables, the precise derivation of the associated classical Yang Baxter equation is thus a subtle procedure requiring the explicit knowledge of the Lax matrix and r -matrix. Obtaining the specific form associated with the GNF equation is not a priori guaranteed.

By contrast there are fewer results regarding r -matrices depending on non-Poisson commuting sets of dynamical variables (hereafter loosely denoted “ p, q dependent r -matrices”). Indeed few examples are known, even less explicitly so, no associated classical “dynamical” Yang Baxter equation has been derived, let alone any quantization thereof. Note at this point that we expect any such quantization to have very unusual features compared to the “standard” dynamical case, involving as it should *non-commutative* deformation parameters p, q (instead of the sole c -number parameters q) inside the generalized R matrix.

The study of such r -matrices is thus clearly a very challenging and promising issue in the domain of integrable systems and this paper will present an attempt at expanding the current state of knowledge about them by constructing new examples of Lax matrices and their associated r -matrices.

To position the problem, let us first recall a few known examples where the r -matrix exhibits these dependance: the complex sine Gordon case [3] (explicit pair r, s but no decoupled Yang Baxter equation); the elliptic Calogero Moser model [14, 15] in its spectral parameter-free formulation [16] (nonexplicit); the BC_n Ruijsenaars Schneider Lax matrix [17] (nonexplicit); and possibly the recently proposed 2x2 Lax matrix associated with special solutions of the Camassa Holm equation [18].

The simplest example (albeit nonexplicit yet) is provided by the Ragnisco-Bruschi [19] construction of the r -matrix for the Lax matrix yielding the Calogero-Françoise (CF) Hamiltonian [20]. The Lax matrix reads:

$$\mathbf{L} = \sum_{i,j} L_{ij} \mathbf{e}_{ij} ; L_{ij} = \sqrt{p_i p_j} A(q_i - q_j) ; \text{ with } A(q) = \cosh(\nu q/2) + \rho \sinh(\nu |q/2|) \quad (1.1)$$

The CF Hamiltonian is $Tr(\mathbf{L}^2)$. This dynamical system may be viewed as a generalization of both Camassa-Holm peakon integrable system (where $A(z) = \exp(\nu|z|)$), describing the dynamics of specific singular “peaked” solutions to the famous Camassa Holm shallow wave fluid equation [21, 22, 23], and the related Calogero system [24] (where $A(z) = \cos(z)$).

We shall be classifying here the Lax matrices à la Calogero-Françoise admitting an r -matrix. We shall in this paper restrict ourselves to Lax matrices where the diagonal potential A_{ii} is a constant (we shall comment upon this at the end) and A is an even function.

The problem will then be solved by first imposing and solving a necessary condition on A derived from the vanishing of the Poisson bracket $\{Tr\mathbf{L}, Tr\mathbf{L}^2\}$ and $\{Tr\mathbf{L}^2, Tr\mathbf{L}^3\}$; then explicitey constructing the r -matrix will show that any such solution be indeed integrable. Some further comments and perspectives shall be added at the end. Not surprisingly the periodic peakon potential [25] will be obtained as one solution.

2 The model

We assume the following form for the Lax matrix:

$$\mathbf{L} = \sum_{i,j} \sqrt{p_i p_j} A_{i,j} \mathbf{e}_{ij}, \quad \text{with } \begin{cases} A_{i,i} = a_i \text{ some complex constant} \\ A_{i,j} = A(q_i - q_j) \text{ for } i \neq j \end{cases} \quad (2.1)$$

As usual $\mathbf{e}_{ij}$ denotes the $n \times n$ matrix representation of $gl(n)$. We require that A be an even complex function of a real variable, with isolated singularities (more precisely separated from any other such point by a distance strictly bounded from below), at least D_1 around regular points and such that A^2 be a piecewise D_2 function.

2.1 Necessary conditions

Starting from the formulae for the first three Hamiltonians defined from $\mathbf{L}$:

$$\begin{aligned} H_1 &= Tr\mathbf{L} = \sum_i p_i A_{i,i} = \sum_i p_i a_i \\ H_2 &= Tr\mathbf{L}^2 = \sum_{i,j} p_i p_j A_{i,j} A_{j,i} = \sum_i p_i^2 a_i^2 + \sum_{i \neq j} p_i p_j A^2(q_i - q_j) \\ H_3 &= Tr\mathbf{L}^3 = \sum_{i,j,k} p_i p_j p_k A_{i,j} A_{j,k} A_{k,i} = \\ &= \sum_i p_i^3 a_i^3 + 3 \sum_{i \neq j} p_i^2 p_j a_i A^2(q_i - q_j) + \sum_{i \neq j \neq k} p_i p_j p_k A(q_i - q_j) A(q_j - q_k) A(q_k - q_i) \end{aligned} \quad (2.2)$$

we impose simultaneous vanishing of all Poisson brackets between them as a necessary condition for integrability.

With the convention $\{p_i, q_j\} = \delta_{i,j}$, one gets

$$\{H_1, H_2\} = 2 \sum_{i \neq j} p_i p_j (a_i - a_j) A(q_i - q_j) A'(q_i - q_j)$$

H_1 and H_2 are in involution if and only if either the potential is a piecewise constant function (a trivial solution, so we will solve excluding this case) or the diagonal part of the potential is uniform: $a_i = a$. Setting all a_i 's to a the Poisson bracket of H_2 and H_3 , after some rearrangements,

reduces to

$$\{H_2, H_3\} = 6 \sum_{i,j,k,l} p_i p_j p_k p_l A_{k,l} (A_{i,l} A_{j,k} - A_{j,l} A_{i,k}) (A_{l,i} A'_{l,j} - A_{l,j} A'_{l,i})$$

with $A'_{i,j} = A'(q_i - q_j)$ for $i \neq j$ and $A'_{i,i} = 0$. In particular the $p_a^2 p_b p_c$ coefficient is a multiple of: $(A_{b,a} A_{a,c} - a A_{b,c}) [(A_{a,b}^2 - A_{a,c}^2) A'_{b,c} + (A_{a,b} A'_{a,b} + A_{a,c} A'_{a,c}) A_{b,c} - a (A_{a,b} A'_{a,c} + A_{a,c} A'_{a,b})]$.

Let us denote the differences in positions in terms of $x = q_a - q_b$ and $y = q_c - q_a$; the commutation of H_2 and H_3 yields:

$$A(x) A(y) = a A(y + x) \quad (2.3)$$

or

$$(A^2(x) - A^2(y)) A'(y + x) + (A A'(y) - A A'(x)) A(y + x) = a (A(x) A'(y) - A(y) A'(x)) \quad (2.4)$$

Note that, if for x and y in the vicinity of some x_o and y_o equation (2.3) is satisfied, then $A'(x) A(y) = A(x) A'(y) = a A'(y + x)$ yielding also $A^2(x) A'(y + x) = A A'(x) A(y + x)$ and $A^2(y) A'(y + x) = A A'(y) A(y + x)$. So equation (2.4) has to be satisfied in the full plane x, y except perhaps in some isolated points (necessarily singular for A).

Introducing the variables $s = y + x$ and $d = y - x$, as well as the three functions

$D(s, d) = A^2(y) - A^2(x)$, $F(s, d) = 2 A(y) A(x)$ and $G = \partial_d F$, equation (2.4) now reads:

$$\partial_s D(s, d) A(s) - D(s, d) A'(s) = a G(s, d) \quad (2.5)$$

In the vicinity of a regular point, the derivation with respect to d also yields:

$$\partial_d \partial_s D(s, d) A(s) - \partial_d D(s, d) A'(s) = a \partial_d G(s, d) \quad (2.6)$$

Eliminating $A'(s)$ from equations (2.5) and (2.6) and defining $\Delta = D \partial_d \partial_s D - \partial_d D \partial_s D$, one gets:

$$\Delta(s, d) A(s) = a (D(s, d) \partial_d G(s, d) - \partial_d D(s, d) G(s, d)) \quad (2.7)$$

Note that $D(s, d) = D(d, s)$ directly from its definition since the exchange of s and d corresponds to the transformation of x into $-x$ and A is an even function. Hence Δ is also a symmetric function and one gets from (2.7):

$$\Delta(s, d) A(d) = a (D(s, d) \partial_s H(s, d) - \partial_s D(s, d) H(s, d)) \quad (2.8)$$

with $H = \partial_s F$ (note that F is also symmetric in s and d).

Actually, by direct computation, one obtains that the two rhs of equations (2.7) and (2.8) are equal. Let us denote them by $a K$ with K the following symmetric function:

$$K(s, d) = D \partial_d \partial_d F - \partial_d D \partial_d F = D \partial_s \partial_s F - \partial_s D \partial_s F \quad (2.9)$$

Since we have excluded from the begining any piecewise constant potential, we obtain $\Delta = 0$ as a necessary condition:

$$\Delta = D \partial_d \partial_s D - \partial_d D \partial_s D = 0 \quad (2.10)$$

This very equation can be solved on any regular domain of the plane, so we get *piecewisely*:

$$D(s, d) = \alpha(s) \beta(d) \quad (2.11)$$

with α and β two D_1 -functions on the interval of s , respectively d , where they build D . Note that if we change the domain of the plane where we solve the equation the functions α and β are not necessarily the same functions as in the first domain, even if they happen to be defined at some common value of s (or d).

Remark that since $D(s, d) = A^2(y) - A^2(x)$ and since A^2 has been supposed piecewisely D_2 , α and β are actually D_2 , one thus gets *piecewisely*:

$$\frac{1}{4} ((A^2)''(y) - (A^2)''(x)) = \alpha''(s) \beta(d) = \alpha(s) \beta''(d) \quad (2.12)$$

So for any pair of functions α and β , there exists some complex constant ν such that

$$\alpha''(s) = \nu^2 \alpha(s), \quad \beta''(d) = \nu^2 \beta(d) \text{ and } (A^2)''(y) - 4\nu^2 A^2(y) = (A^2)''(x) - 4\nu^2 A^2(x) \quad (2.13)$$

Note that the last equality holds for any couple of regular points. One finally obtains the following form for the square of the potential:

$$A^2(x) = \gamma + \lambda_x e^{2\nu_x x} + \mu_x e^{-2\nu_x x} \quad (2.14)$$

with γ some complex constant and ν_x , λ_x and μ_x three piecewise constant functions (to discriminate between λ and μ we will assume $\text{Re}(\nu_x) \geq 0$). Reinserting this form into (2.10) yields:

$$(\nu_x^2 - \nu_y^2) (\lambda_x e^{2\nu_x x} + \mu_x e^{-2\nu_x x}) (\lambda_y e^{2\nu_y y} + \mu_y e^{-2\nu_y y}) + 4(\nu_y^2 \lambda_y \mu_y - \nu_x^2 \lambda_x \mu_x) = 0 \quad (2.15)$$

One obtains that ν_x is actually a complex constant, i.e. $\nu_x = \nu_y$, that we will accordingly denote by ν in the following, we can assume that it is not zero since we have already discarded the piecewise constant potential. More interestingly the product $\lambda_x \mu_x$ is also constant and we shall now call it ρ^2 (up to a normalization factor).

One then easily shows that $\rho = 0$ is essentially not compatible with the assumption of an even potential and leads to A constant. In the following we will thus assume $\rho \neq 0$.

Let us now introduce another piecewise constant function θ_x , parametrize $\lambda_x \mu_x = \frac{\rho^2}{16}$ by $\lambda_x = \frac{\rho}{4} e^{-\nu \theta_x}$ and $\mu_x = \frac{\rho}{4} e^{\nu \theta_x}$, and get:

$$\begin{aligned} A^2(x) &= \rho (\cosh^2(\nu(x - \theta_x/2)) - \cosh^2(\nu z_o)) \\ &= \rho \sinh(\nu(x + z_o - \theta_x/2)) \sinh(\nu(x - z_o - \theta_x/2)) \end{aligned} \quad (2.16)$$

with z_o a complex constant.

This expression of A^2 yields:

$$\begin{aligned} D(s, d) &= \rho (\cosh^2(\nu(y - \theta_y/2)) - \cosh^2(\nu(x - \theta_x/2))) \\ &= \rho \sinh(\nu(s - (\theta_y + \theta_x)/2)) \sinh(\nu(d - (\theta_y - \theta_x)/2)) \end{aligned} \quad (2.17)$$

Using this expression in equation (2.5), one shows that:

$$\partial_d(A(x) A(y)) = \mathcal{A}(s) \nu \sinh(\nu(d - (\theta_y - \theta_x)/2))$$

with $\mathcal{A}(s)$ some function of s . Hence there exists some function $\mathcal{B}$ of s such that:

$$A(x) A(y) = \mathcal{A}(s) \cosh(\nu(d - (\theta_y - \theta_x)/2)) + \mathcal{B}(s) \quad (2.18)$$

From (2.16), one also gets:

$$\begin{aligned}
A^2(x) A^2(y) &= \rho^2 \sinh(\nu(x + z_0 - \theta_x/2)) \sinh(\nu(y + z_0 - \theta_y/2)) \\
&\quad \sinh(\nu(x - z_0 - \theta_x/2)) \sinh(\nu(y - z_0 - \theta_y/2)) \\
&= \rho^2/4 (\cosh(\nu(s + 2z_0 - (\theta_y + \theta_x)/2)) - \cosh(\nu(d - (\theta_y - \theta_x)/2))) \\
&\quad (\cosh(\nu(s - 2z_0 - (\theta_y + \theta_x)/2)) - \cosh(\nu(d - (\theta_y - \theta_x)/2)))
\end{aligned} \tag{2.19}$$

The compatibility between (2.18) and (2.19) imposes:

$$\cosh(\nu(s + 2z_0 - (\theta_y + \theta_x)/2)) = \cosh(\nu(s - 2z_0 - (\theta_y + \theta_x)/2))$$

or equivalently $\sinh(\nu 2z_0) = 0$ restricting the constant $\cosh^2(\nu z_0)$ to be either 0 or 1. Up to a shift on θ_x , we have obtained that the potential is of the following form:

$$A(x) = A_o \cosh(\nu(x - \theta_x/2)) \tag{2.20}$$

with A_o a complex constant. Equation (2.5) now reduces to an equation on the piecewise constant function θ_x (defined modulo $4i\pi/\nu$):

$$A_o \cosh(\nu(\theta_x + \theta_y - \theta_{x+y}/2)) = a \tag{2.21}$$

The only other condition is the parity of A , imposing $\theta_{-x} = -\theta_x$. In particular this is true for $x = 0$ where A is thus continuous, but generically not differentiable.

So either $\theta_x = \theta_{0+} = -\theta_{-x}$ for all positive x , or it admits a first strictly positive discontinuity in x_1 , and reads $\theta_x = (2n_x + 1)\theta_{0+}$, with n_x the integer quotient of x divided by x_1 ($x = n_x x_1 + r_x$, $r_x \in [0, x_1[$ and $n_x \in \mathbb{Z}$).

Finally, we have established the following proposition:

Proposition 1

A Lax matrix of type (2.1) which defines a completely integrable system can at most depend on three complex parameters (A_o, ν and θ_{0+}) and possibly a strictly positive real one (x_1). It has to be of the following form:

$$\mathbf{L} = \sum_{i,j} \sqrt{p_i p_j} A_o \cosh(\nu(q_i - q_j - \frac{1}{2} \theta_{(q_i - q_j)})) \mathbf{e}_{ij}, \tag{2.22}$$

$$\text{with either } \theta_x = \text{sign}(x) \theta_{0+} \quad \text{or} \quad \begin{cases} \theta_x = (2n_x + 1) \theta_{0+} \text{ for } x = n_x x_1 + r_x, \\ r_x \in [0, x_1[, \text{ and } n_x \in \mathbb{Z} \end{cases}$$

The first set of solutions with $\theta_x = \text{sign}(x) \theta_{0+}$ corresponds exactly to the Calogero-François Lax matrix (1.1). Note that within the new set of solutions, if one put $x_1 = \theta_{0+}$, one gets a non trivial continuous periodic potential.

2.2 The r -matrix

We will now establish Liouville-integrability for the Hamiltonians associated with the Lax matrix (2.22) by explicitly constructing the r -matrix.

Following closely the r -matrix derivation in [19] it is easily seen that it hangs upon the following technical lemma:

Lemma

If there exist two odd functions B and C , such that the even function A obey the consistency equation (labeled (2.10) in [19]) where again $s = x + y$:

$$\partial_s(A(x)A(y)) = B(s) + A(s)(C(x) + C(y)) \quad (2.23)$$

the Lax matrix $\mathbf{L} = \sum_{i,j} \sqrt{p_i p_j} A(q_i - q_j) \mathbf{e}_{ij}$ has a linear r -matrix Poisson structure:

$$\{\mathbf{L}_1, \mathbf{L}_2\} = [\mathbf{r}_{12}, \mathbf{L}_1] - [\mathbf{r}_{21}, \mathbf{L}_2] \quad \text{with the standard notations } \mathbf{L}_1 \equiv \mathbf{L} \otimes \mathbf{1} \text{ and } \mathbf{L}_2 \equiv \mathbf{1} \otimes \mathbf{L}$$

and $\mathbf{r}_{12} \equiv \sum_{i,j,k,l} r_{ijkl} \mathbf{e}_{ij} \otimes \mathbf{e}_{kl}$; $\mathbf{r}_{21} = \sum_{i,j,k,l} r_{ijkl} \mathbf{e}_{kl} \otimes \mathbf{e}_{ij}$ given by:

$$\mathbf{r}_{12} = \frac{1}{2} \sum_{i \neq j} C(q_i - q_j) \mathbf{e}_{ij} \otimes (\mathbf{e}_{ij} + \mathbf{e}_{ji}) + \frac{1}{2} \sum_{i,j,k} S_{jk} (\mathbf{e}_{ij} - \mathbf{e}_{ji}) \otimes (\mathbf{e}_{ik} + \mathbf{e}_{ki}) \quad (2.24)$$

S_{jk} are the elements of any symmetric matrix $\mathbf{S}$ solving the algebraic equation:

$$[\mathbf{S}, \mathbf{L}]_{ij} = \sqrt{p_i p_j} B(q_i - q_j) \quad (2.25)$$

Proof: Proof can be obtained from direct verification, once it is established that the Poisson brackets of $\mathbf{L}$ with itself are given uniquely in terms of the function $\partial_s(A(x)A(y))$.

Remark 1

Existence of a solution $\mathbf{S}$ to the algebraic equation (2.25) is obtained by rewriting the defining equation in an orthogonal basis for the symmetric matrix $\mathbf{L}$ when $\mathbf{L}$ is real. If $\mathbf{L}$ is complex symmetric, one needs to assume separately that it can be diagonalized (which is true if $\mathbf{L}$ is in general position). In both cases one also needs to assume that the eigenvalues are non degenerate. Note that the issue of degenerate eigenvalues for a Lax matrix is in any case a delicate one and needs a case-by-case treatment.

Remark 2

$\mathbf{S}$ is in any case not unique, since in particular any polynomial in $\mathbf{L}$ yields a symmetric matrix commuting with $\mathbf{L}$ itself.

We are currently working on an explicit formulation of solutions to equation (2.25).

We now state the key result of this section:

Proposition 2

The function $A(x)$ in (2.20) obeys the r -matrix consistency equation (2.23) with the functions:

$$\begin{aligned} B(x) &= \frac{1}{2}(A'(x)A(0) - \frac{\theta_x}{\theta_{0+}} A(x)A'(0)) \\ &= \frac{\nu A_0^2}{2}(\sinh(\nu(x - \theta_x/2)) \cosh(\nu\theta_{0+}/2) + \frac{\theta_x}{\theta_{0+}} \cosh(\nu(x - \theta_x/2)) \sinh(\nu\theta_{0+}/2)) \end{aligned} \quad (2.26)$$

$$\text{and } C(x) = \frac{1}{2} \frac{\theta_x}{\theta_{0+}} A'(0) = -\frac{\nu A_o}{2} \frac{\theta_x}{\theta_{0+}} \sinh(\nu \theta_{0+}/2) \quad (2.27)$$

Oddness of functions B and C follows from $\theta_{-x} = -\theta_x$. The proof proceeds by direct checking of the “addition” formula (2.23), paying due attention to the consistency of this addition for the step function θ_x .

Hence all necessary potentials A yield a Lax matrix which exhibits an r -matrix structure of the form obtained by Ragnisco-Bruschi, albeit with periodic or more generally pseudoperiodic coefficient functions B and C . We have thus completely classified the integrable classical Lax operators of the Calogero-Françoise form.

3 Remarks and perspectives

1. We have obtained a new set of pseudoperiodic potentials as a result of our systematic search for even Calogero-Françoise type potentials. It would be interesting to know how to formulate alternatively algebraic integrability properties (extension of the Abel maps and associated hyperelliptic curves [25]) for such pseudoperiodic potentials. In principle the conserved Hamiltonians should be moduli of the associated curve. The possible connection with the pseudoperiodic *solutions* derived in e.g. [23] may also be interesting.

Of course among these potentials one recovers the fully periodic peakon potential derived by Beals et al [25]. Here we prove its r -matrix (hence Liouville) integrability whereas [25] had proven algebraic integrability in the above sense.

2. Interpretation of the pseudoperiodic “peakons” in the frame of Camassa Holm equation may be interesting, possibly as solutions for a system in a finite volume with some specific boundary conditions.

3. It is easily checked that a folding procedure exists which consistently yields new integrable systems from these initial pseudoperiodic ones. Starting from the $N = 2n(+1)$ -body system with positions labeled now from $-n$ to $+n$ (without/with 0) one proves immediately that the folding constraints $p_i = p_{-i}$, $q_i = q_{-i}$ are invariant by evolution under all even (resp. odd) degree Hamiltonians. Hence the reduced dynamical system itself has n invariant Poisson commuting Hamiltonians under the reduced Poisson bracket. Its Lax matrix takes the form:

$$\mathbf{L} = \sum_{i,j=1(0)}^n L_{ij} (\mathbf{e}_{ij} + \mathbf{e}_{-i,j} + \mathbf{e}_{i,-j} + \mathbf{e}_{-i,-j}) \text{ with:}$$

$$L_{ij} = \sqrt{p_i p_j} \left(\cosh \frac{\nu(q_i - q_j)}{2} + \rho \sinh \frac{\nu|q_i - q_j|}{2} \right) \quad (3.1)$$

Here one first (rather trivial) possibility of extension of the strict Calogero Françoise framework is made explicit.

4. In order to proceed towards a deduction of the form for the Yang-Baxter type equation one key point now is to get an explicit form for the r -matrix by solving the matrix equation for $\mathbf{S}$. Partial results are now available and we hope to soon have the general form of this r -matrix.

Acknowledgements

We wish to thank Eric Ragoucy for his interest and his collaboration in unraveling the algebraic equation (2.25). J.A. thanks LAPTH Annecy for their kind hospitality.
